

Screened encodings and their cost after transpilation to a rz, sx, x, cx basis. 20 configurations, 1-8 qubits, at most depth 35 and 28 two-qubit gates: the arm was rejected by its own screens, not by circuit size. The unentangled series coincide -- with its entangling layer removed zz is z, which is what makes it the control.

dense-angle: two features per qubit [4 features, 2 qubits, logical depth 6, transpiled depth 12]

z: product encoding, no entanglement [2 features, 2 qubits, logical depth 4, transpiled depth 7]

zz: pairwise phase, linear entanglement [2 features, 2 qubits, logical depth 10, transpiled depth 14]
